

Measurement and simulation of volatile particle emissions from military aircraft

WP 1625, WP-1626, WP-1627

Allen Robinson
Carnegie Mellon University

Presented at Partners in Environmental Technology Technical Symposium & Workshop Washington DC November 30, 2011.

Report Documentation Page		Form Approved OMB No. 0704-0188
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

14. ABSTRACT Many military airfields are located in nonattainment areas for fine particulate matter (PM2.5) but the contribution of aircraft emissions to local and regional PM2.5 concentrations is not well understood. Aircraft directly emit particles, but the vast majority of the emissions are gases and vapors, some of which undergo gas-to-particle conversion in the atmosphere. Primary particulate matter is defined as directly emitted particles plus any material that condenses into the particle phase without undergoing chemical reactions. This latter component is often referred to as volatile particulate matter. Secondary particulate matter is formed from oxidation of gas-phase species such as sulfur dioxide and organics. To develop effective control strategies one must understand the overall contribution of military aircraft emissions to ambient particulate matter? both direct particle emissions and particulate matter formed in the atmosphere. To assist the Department of Defense in meeting the current and future regulations related to PM2.5 concentrations, SERDP initiated a research program in 2007 to investigate volatile particulate matter emissions. Three projects were funded within this program; the lead organizations of these programs were Aerodyne Research Inc., Carnegie Mellon University, and Oak Ridge National Laboratories. The projects included experiments to measure the formation and atmospheric evolution of volatile particulate matter, the development volatile emission models, and the evaluation of new instrumentation and experimental techniques. This presentation will summarize the major findings of the SERDP volatile particulate matter program, including the contribution of lubricating oil and atmospheric oxidation to volatile particulate matter emissions.

Many military airfields are located in nonattainment areas for fine particulate matter ($PM_{2.5}$), but the contribution of aircraft emissions to local and regional $PM_{2.5}$ concentrations is not well understood. Aircraft directly emit particles, but the vast majority of the emissions are gases and vapors, some of which undergo gas-to-particle conversion in the atmosphere. Primary particulate matter is defined as directly emitted particles plus any material that condenses into the particle phase without undergoing chemical reactions. This latter component is often referred to as volatile particulate matter. Secondary particulate matter is formed from oxidation of gas-phase species such as sulfur dioxide and organics. To develop effective control strategies one must understand the overall contribution of military aircraft emissions to ambient particulate matter—both direct particle emissions and particulate matter formed in the atmosphere.

To assist the Department of Defense in meeting the current and future regulations related to $PM_{2.5}$ concentrations, SERDP initiated a research program in 2007 to investigate volatile particulate matter emissions. Three projects were funded within this program; the lead organizations of these programs were Aerodyne Research Inc., Carnegie Mellon University, and Oak Ridge National Laboratories. The projects included experiments to measure the formation and atmospheric evolution of volatile particulate matter, the development volatile emission models, and the evaluation of new instrumentation and experimental techniques. This presentation will summarize the major findings of the SERDP volatile particulate matter program, including the contribution of lubricating oil and atmospheric oxidation to volatile particulate matter emissions.

What is volatile PM?

(Kinsey et al. EST 2011)

(Kinsey et al. EST 2011)

How does volatile PM evolve in the atmosphere?

Spatial / Temporal Scales

SERDP Volatile PM Projects

Oak Ridge National Lab Team (WP-1627)

- Measurement Systems
 - Thermodenuder
 - Dilution sampler & aging chamber
- Measurements of gas turbine engine emissions

0 → 2 km

0 → 1 km

0.1 → 50 km

Aerodyne Team (WP-1625)

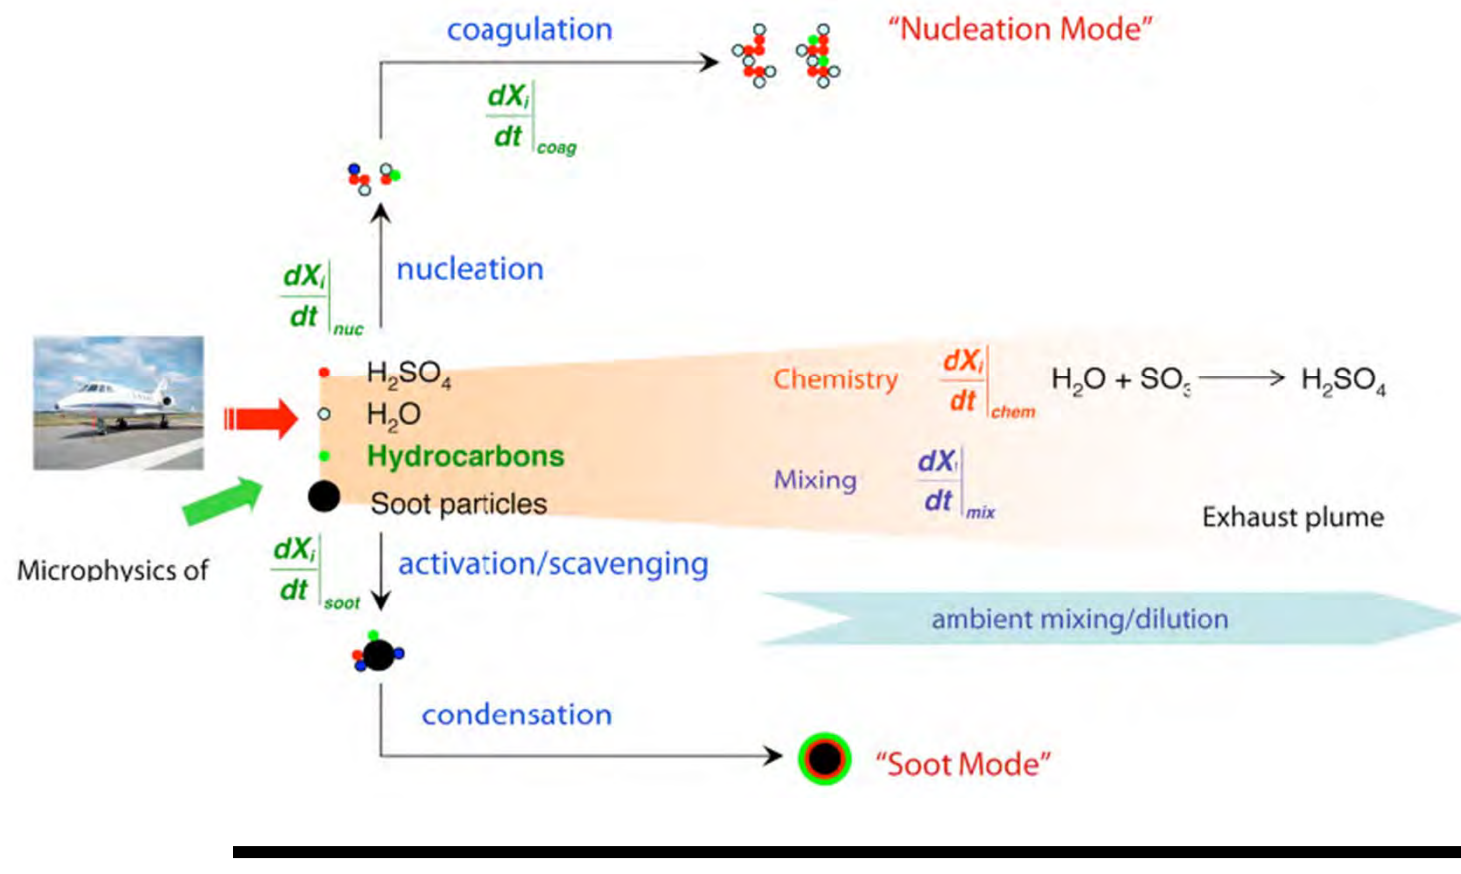

- Microphysical Kinetic Model for Plume
- Contributions of lube oil
- Laboratory studies of specific HCs and Sulfate
- Combustor system studies

Carnegie Mellon University Team (WP-1626)

- Measurement of PM in engine exhaust
- Aging in "smog" chamber
- Modeling of gas-particle partitioning and SOA production

Microphysical Modeling of Near-Field Evolution of Volatile PM

WP-1625

~ 1 km

Predicted evolution of nucleation mode

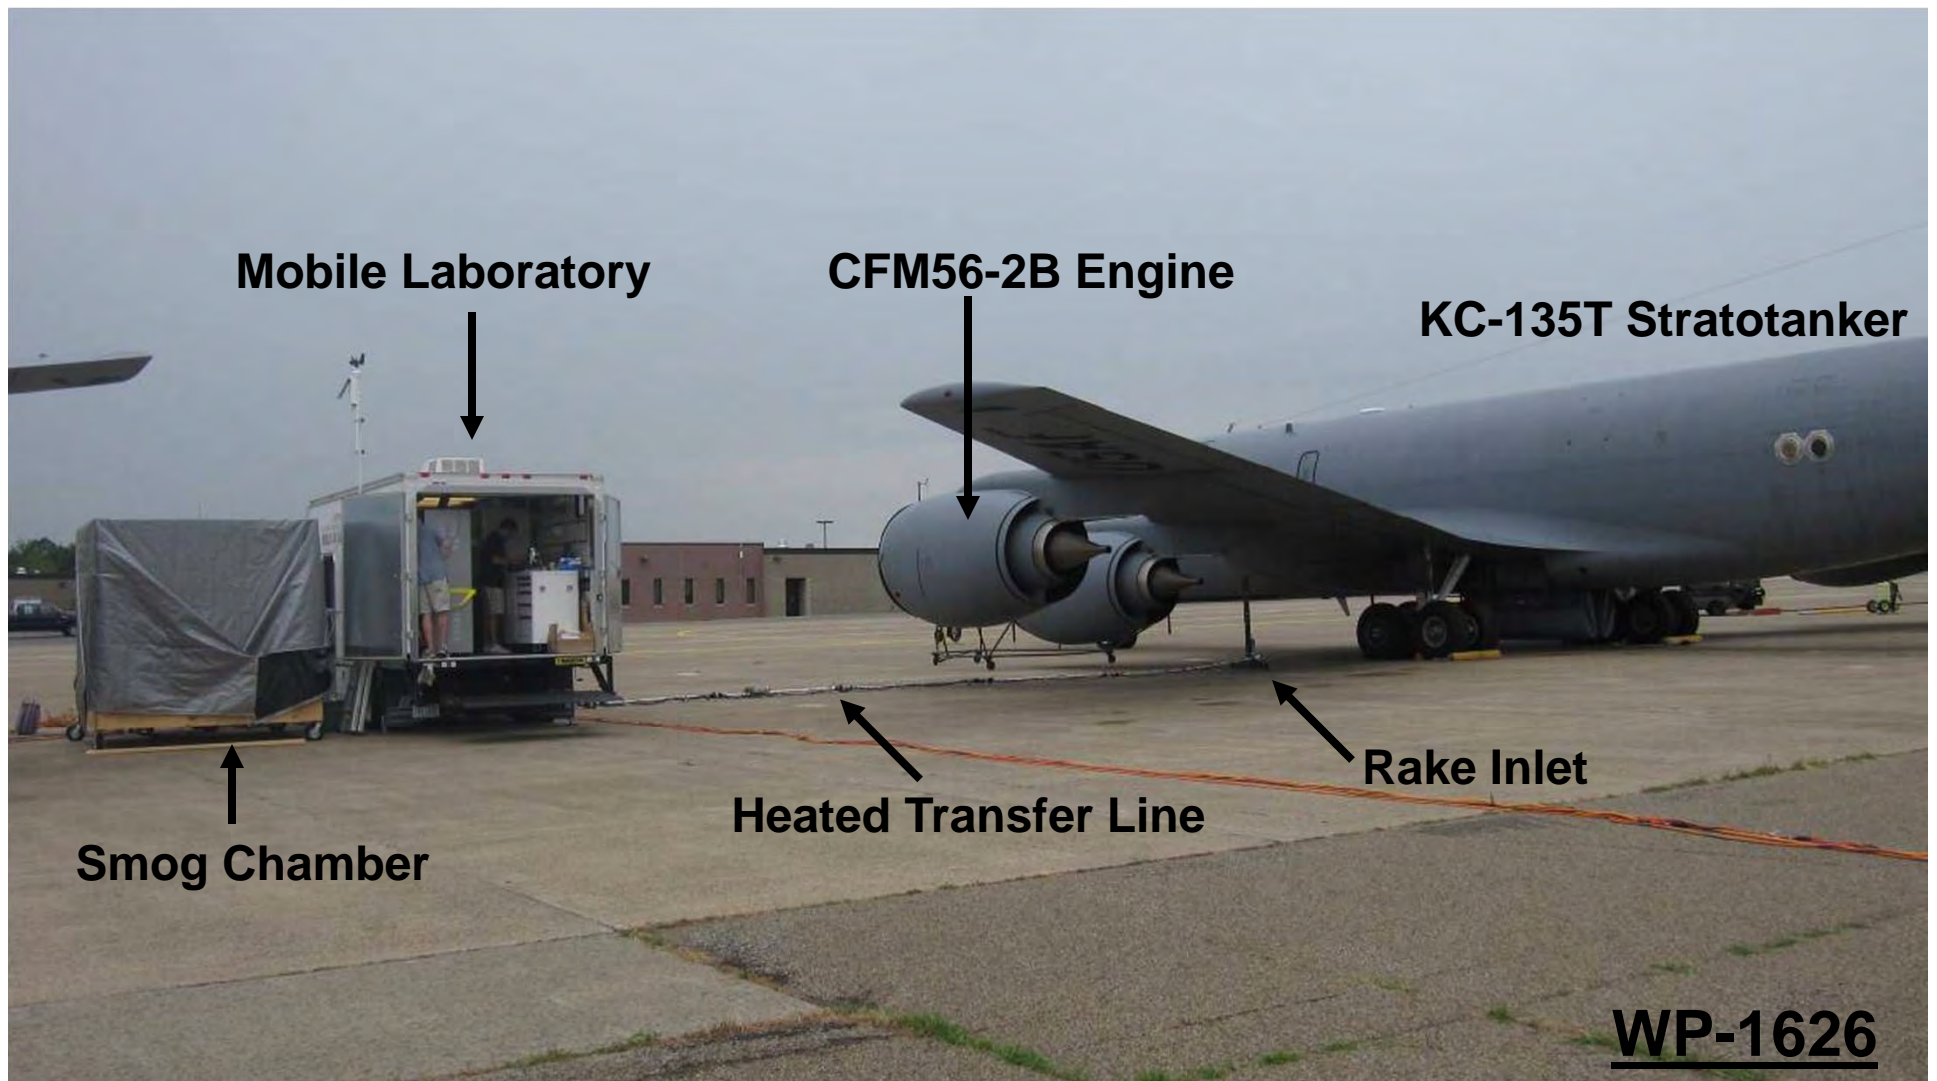

Predicted Particle Composition in Aircraft Plume

Findings:

- Highly Dynamic Systems
- Nucleation driven by sulfuric acid and water
- Hydrocarbons critical for growth

Staged Testing

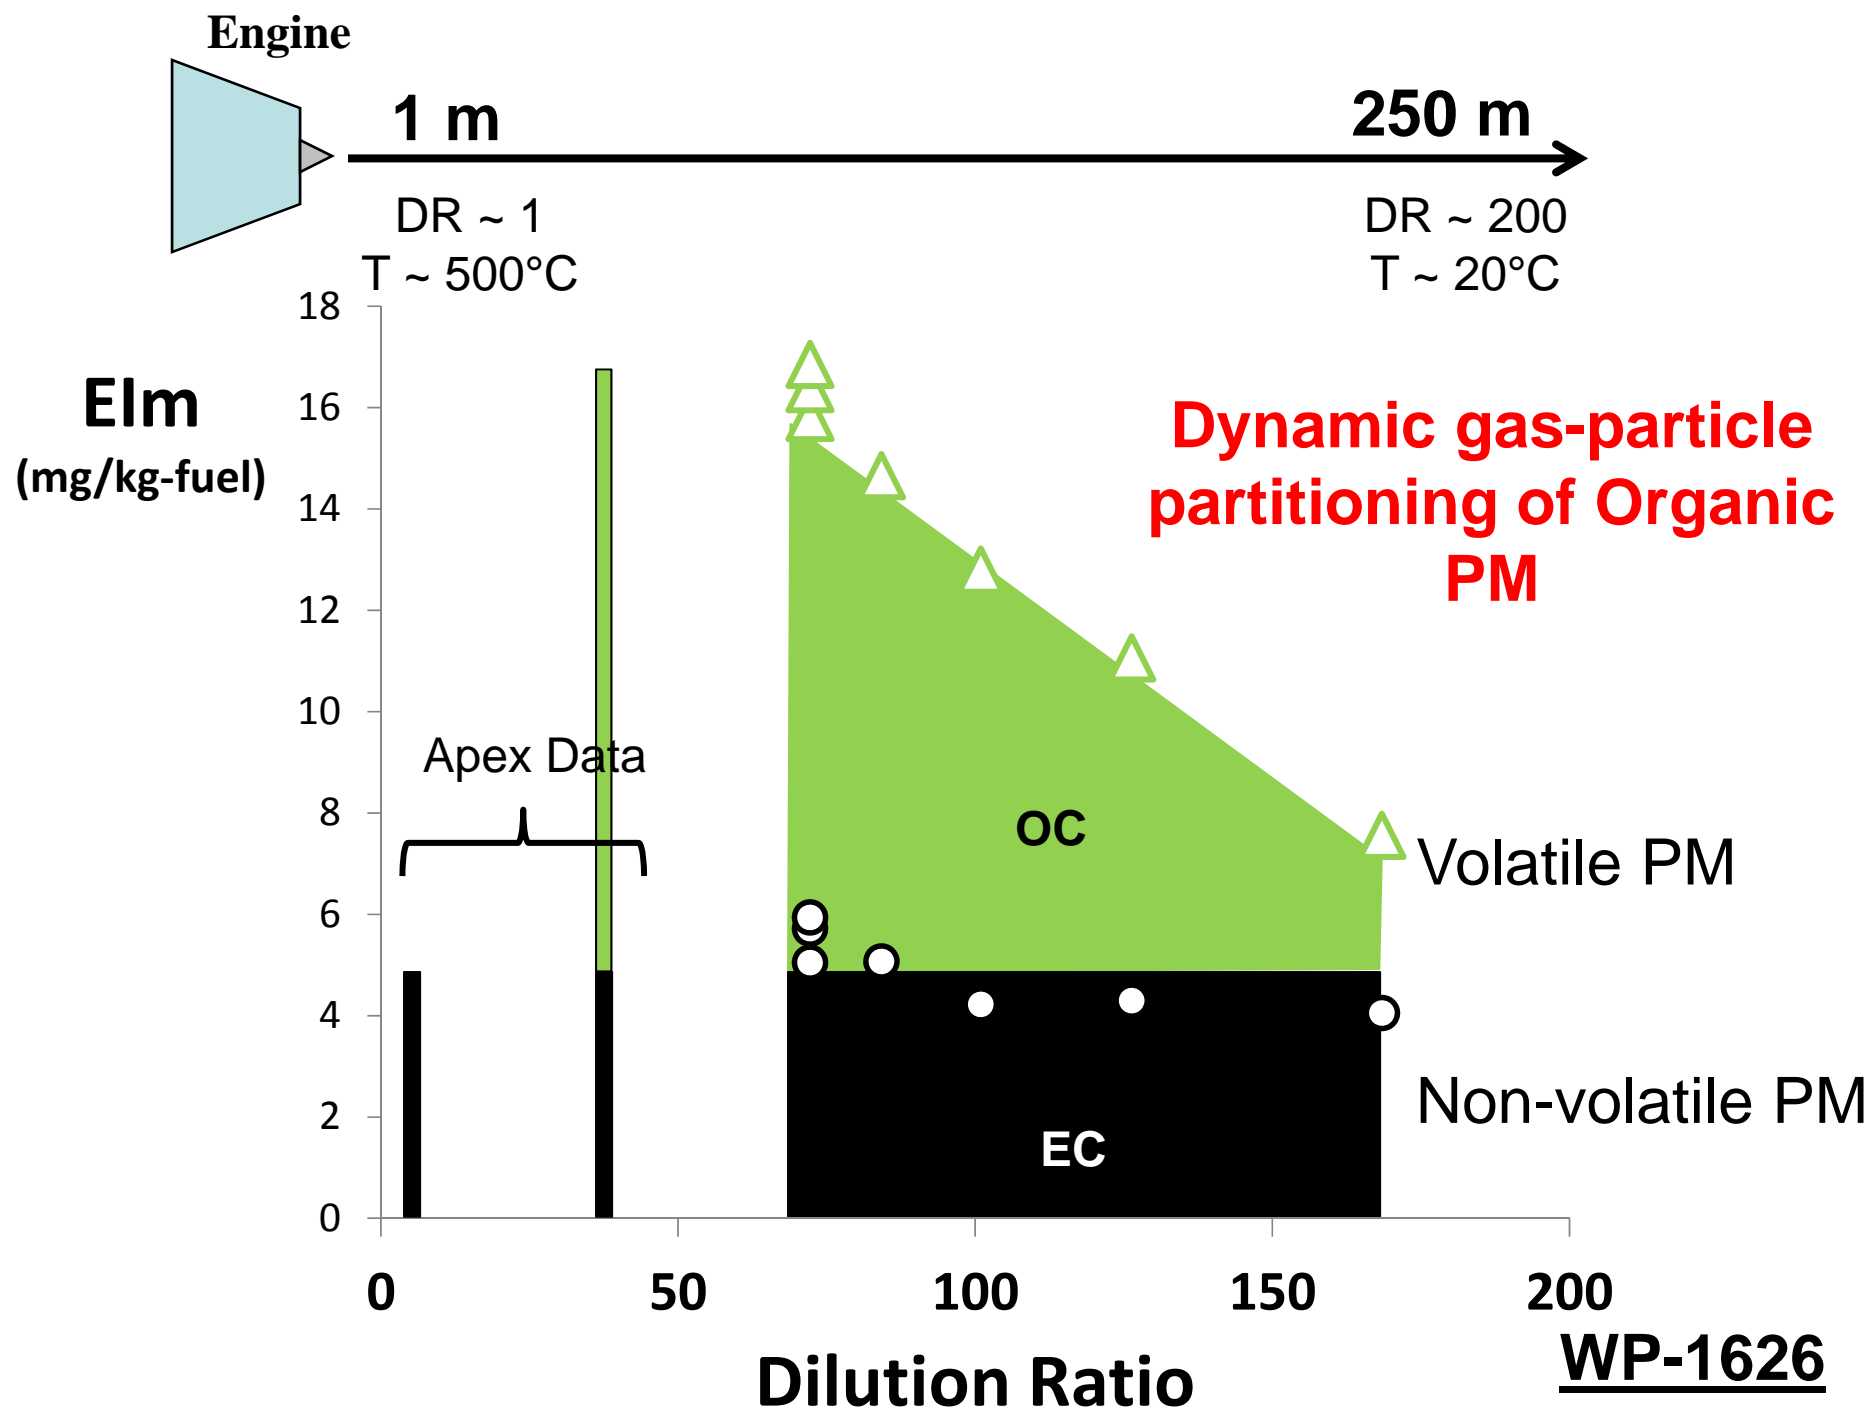

WP-1626

Amount of volatile PM emissions vary with atmospheric conditions

What are effects of photo-chemical aging?

Taking off the chamber cover

WP-1626

Primary PM in Chamber

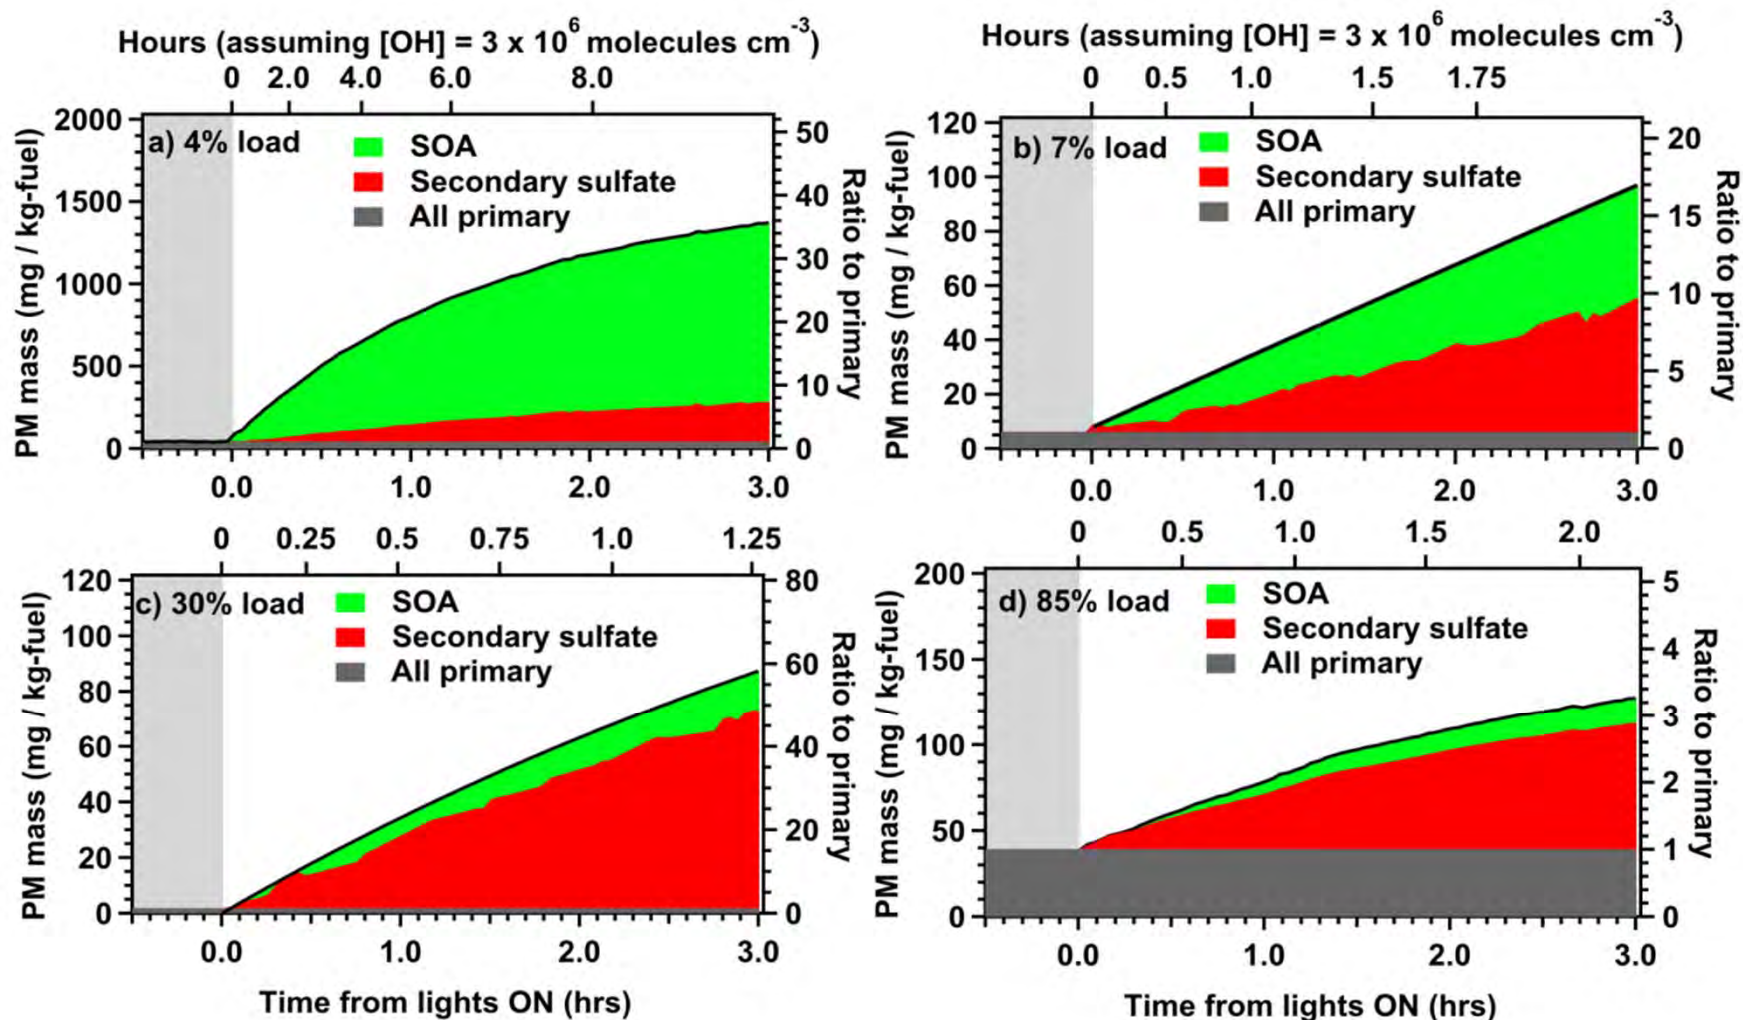

Secondary aerosol production overwhelms primary emissions

Ave [OH] $\sim 6 \times 10^6$ molec/cm³

At every engine load

Effect of Fuel Composition on Secondary Aerosol

Modeling Secondary Aerosol Formation

Parameterizing Yields

Predicted Evolution Yields

Secondary PM dominant at urban and regional scales

Instrumentation development

Dilution sampler

New Thermodenuder

- Low particle losses
- Portability
- Turnkey

Lubrication Oil and Volatile PM

Mass spectra of lube oil

Findings:

The emission of lubrication oil varies significantly among the aircraft engines with different designs

Contribution from oil can be dominant in organic PM emission in some cases.

Key findings SERDP Volatile PM

- Volatile PM highly dynamic system in atmosphere
- Secondary volatile PM production very significant
- Lube oil important constituent of volatile PM
- New tools:
 - ◆ Detailed microphysical kinetic model for plume soot, sulfate, and organic
 - ◆ Volatility basis set model for gas-particle partitioning of primary organic aerosol and production of secondary organic aerosol (SOA) in atmosphere
 - ◆ Dilution sampler, thermodenuder, and smog chamber techniques
- Archival Papers: 7 published, 4 near submission, others in process

Primary PM Emissions

CFM56 with Engine Load

T63 with Fuel Composition
